EchoPulse

EchoPulse is a conversational AI designed to diagnose a medical emergency and walk a user through performing required first-aid procedures that they may not be trained in, such as CPR. It is intended to simulate an emergency services operator, in the event that the user is too remote and cannot call emergency services.

A small on-device LLM will handle verbal conversation, but all diagnosis and first-aid procedures will be outsourced to a rule-based AI. This dramatically reduces the odds of hallucination, whilst also allowing the application to operate with minimal computational strain and relatively low on-device storage costs.
